

HIGH FREQUENCY PULSE GENERATOR FOR
AN IMPLANTABLE NEUROSTIMULATOR

ABSTRACT

5 The invention is directed to a method and apparatus for
electrically stimulating tissue. Many typical devices suffer
from charge build-up on blocking capacitors when stimulating
tissue at higher frequencies. The invention actively drives the
discharge of the blocking capacitors, reducing the discharge
10 time. As a result, stimulating pulses may be delivered at
higher frequencies. Actively discharging the blocking
capacitors may be accomplished with an asymmetric reverse pulse.
This reverse pulse may be provided by a switching circuitry that
reverses the polarity applied to the electrodes or couples a
15 pulse from a second pulse generator to the electrodes.
